SUMMARY OF CIRCLE THEOREMS

2

Theorem 1

[line from centre to mdpt chord]

if line from centre
cuts the chord in half
then the line is a radius

if radius meets the
chord at 90°
then the radius
cuts the chord in half

Theorem 2

3

[line from centre to midpoint chord]

if line from centre cuts the chord in half
then the line is a diameter

and

if the diameter meets the chord at 90°
then the radius cuts the chord in half

Theorem 3

4

[\angle at centre = $2 \times \angle$ at circ.]

if the angle at the centre subtended by arc / chord AB then the angle subtended to the circumference of the circle by the same arc / chord AB will be half the angle at the centre

if the angle at the circumference is subtended by the chord / arc AB then the angle subtended to the centre of the circle by the same chord / arc AB will be double the angle at the circumference of the circle

can look like this.

Theorem 4

5

[\angle 's subtended by = chord]

NOTE: thrm 4
and thrm 5
are proof of
cyclic quads.

if an angle is
subtended by the
same chord (AB or CD)

then any other angle
subtended by the
same chord will be
equal to that angle

another application:

[= chords, subtend = \angle 's]

NOTE: Angles can
be subtended
by a chord or an arc

if: the chords are equal
in length

then: the angles subtended
by the chords (in the
same circle) will be
equal.

Theorem 5

6

[opp. \angle 's cyclic quad. supp.]

if: Opposite angles are part of a cyclic quadrilateral (all four points in the same circle)

then: the angles will be supplementary ($= 180^\circ$)

if: opposite angles add up to 180° (supplementary)

then: the shape is a cyclic quad

$$a + c = 180^\circ$$

$$b + d = 180^\circ$$

$$a + b + c + d = 360^\circ$$

NOTE:

This is NOT a cyclic quad:

Theorem 6

7

[lines of tangent that meet at single point
= length]

if: AB and CB are tangents to the circle and they meet at point B

then: AB and CB are equal in length

Theorem 7

8

[tan - chord thrm]

if: AB is a tangent
to the circle

then: the angle between
the chord and the tangent
(x_1) will be equal to
the angle opposite that
same chord (x_2)

NOTE: y_1 is
also = y_2

[converse tan - chord thrm]

→ this is the reverse
of the tan-chord
thrm.

if: the angle opposite
the chord is equal
to the angle between
the chord and the line
CD

then: CD is a tangent
to the circle

3 WAYS TO PROVE CYCLIC QUADRILATERALS

9

1. [\angle 's subtended by = chord]

if: $\hat{D} = \hat{C}$

then: ABCD is a cyclic quadrilateral

2. [Opp \angle 's of cyclic quad. supp]

if $\hat{A} + \hat{C} = 180$

or $\hat{B} + \hat{D} = 180$

then: ABCD is a cyclic quadrilateral

3. [ext. \angle 's of cyclic quad = opp. int. \angle]

if: $\hat{BDE} = \hat{A}$

then: ABCD is a cyclic quadrilateral

1. [radius \perp tangent]

if: a tangent meets a radius

then: the angle between the tangent and the radius (or diameter) is 90°

2. [\angle on diameter]

if: AB is the diameter

then: $\angle C$ will be 90°

∇
 this is because
 \angle at centre = $2 \times \angle$ at circ
 \therefore diameter = 180°
